D03MAF - NAG Fortran Library Routine Document

Note. Before using this routine, please read the Users' Note for your implementation to check the interpretation of bold italicised terms and other implementation-dependent details.

1 Purpose

D03MAF places a triangular mesh over a given two-dimensional region. The region may have any shape, including one with holes.

2 Specification

```
SUBROUTINE DO3MAF(H, M, N, NB, NPTS, PLACES, INDEX, IDIM, IN,

DIST, LD, IFAIL)

INTEGER M, N, NB, NPTS, INDEX(4,IDIM), IDIM, IN, LD,

1 IFAIL

real H, PLACES(2,IDIM), DIST(4,LD)

EXTERNAL IN
```

3 Description

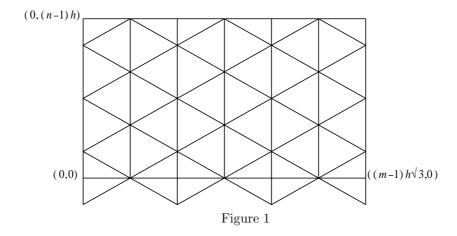

This subroutine begins with a uniform triangular grid as shown in Figure 1 and assumes that the region to be triangulated lies within the rectangle given by the inequalities

$$0 < x < \sqrt{3}(m-1)h$$
, $0 < y < (n-1)h$.

This rectangle is drawn in bold in Figure 1. The region is specified by the user's function IN which must determine whether any given point (x, y) lies in the region. The uniform grid is processed columnwise, with (x_1, y_1) preceding (x_2, y_2) if $x_1 < x_2$ or $x_1 = x_2$, $y_1 < y_2$. Points near the boundary are moved onto it and points well outside the boundary are omitted. The direction of movement is chosen to avoid pathologically thin triangles. The points accepted are numbered in exactly the same order as the corresponding points of the uniform grid were scanned. The output consists of the x, y co-ordinates of all grid points and integers indicating whether they are internal and to which other points they are joined by triangle sides.

The mesh size h must be chosen small enough for the essential features of the region to be apparent from testing all points of the original uniform grid for being inside the region. For instance if any hole is within 2h of another hole or the outer boundary then a triangle may be found with all vertices within $\frac{1}{2}h$ of a boundary. Such a triangle is taken to be external to the region so the effect will be to join the hole to another hole or to the external region.

Further details of the algorithm are given in the references.

5 Parameters

1: H-real

On entry: the required length, h, for the sides of the triangles of the uniform mesh.

2: M — INTEGER

3: N — INTEGER

On entry: values m and n such that all points (x,y) inside the region satisfy the inequalities

$$\begin{array}{ccccc} 0 & \leq & x & \leq & \sqrt{3}(m-1)h, \\ 0 & \leq & y & \leq & (n-1)h. \end{array}$$

Constraint: M, N > 2.

4: NB — INTEGER Input

On entry: the number of times a triangle side is bisected to find a point on the boundary. A value of 10 is adequate for most purposes (see Section 7).

Constraint: $NB \ge 1$.

5: NPTS — INTEGER Output

On exit: the number of points in the triangulation.

6: PLACES(2,IDIM) - real array

On exit: the x and y co-ordinates respectively of the ith point of the triangulation.

7: INDEX(4,IDIM) — INTEGER array Output

On exit: INDEX(1, i) contains i if point i is inside the region and -i if it is on the boundary. For each triangle side between points i and j with j > i, INDEX(k, i), k > 1, contains j or -j according to whether point j is internal or on the boundary. There can never be more than three such points. If there are less, then some values INDEX(k, i), k > 1, are zero.

8: IDIM — INTEGER Input

On entry: the second dimension of the arrays PLACES and INDEX as declared in the (sub)program from which D03MAF is called.

Constraint: IDIM \geq NPTS.

9: IN — INTEGER FUNCTION, supplied by the user.

External Procedure

Output

IN must return the value 1 if the given point (X,Y) lies inside the region, and 0 if it lies outside. Its specification is:

INTEGER FUNCTION IN(X, Y) real X, Y

1: X — real
2: Y — real
Input
Input

On entry: the co-ordinates of the given point.

IN must be declared as EXTERNAL in the (sub)program from which D03MAF is called. Parameters denoted as *Input* must **not** be changed by this procedure.

D03MAF.2 [NP3390/19/pdf]

10: DIST(4,LD) — real array

Work space

11: LD — INTEGER

Input

On entry: the second dimension of the array DIST as declared in the (sub)program from which D03MAF is called.

Constraint: $LD \ge 4N$.

12: IFAIL — INTEGER

Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in Chapter P01) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1

IDIM is too small.

IFAIL = 2

A point inside the region violates one of the constraints (see parameters M and N above).

IFAIL = 3

LD is too small.

IFAIL = 4

 $M \leq 2$.

IFAIL = 5

 $N \leq 2$.

IFAIL = 6

NB < 0.

7 Accuracy

Points are moved onto the boundary by bisecting a triangle side NB times. The accuracy is therefore $h \times 2^{-NB}$.

8 Further Comments

The time taken by the routine is approximately proportional to $m \times n$.

9 Example

The following program triangulates the circle with centre (7.0,7.0) and radius 6.0 using a basic grid size h = 4.0.

9.1 Program Text

Note. The listing of the example program presented below uses bold italicised terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
